Non-Local Approximation

Iris Hammond & Dr. Jeff Ledford

Longwood University Department of Mathematics & Computer Science

Introduction

This project is a continuation of work previously done by Dr. Jeff Ledford. This research extends the non-local approximation schemes found in [1,2,3]. We seek approximands of the form $C_1\phi(x - x_0) + C_2\phi(x - x_1) + \dots + C_n\phi(x - x_{n-1})$ which approximate continuous functions uniformly on closed intervals and interpolate the data $\{(x_j, y_j): j = 0, 1, \dots, n - 1\}$. Our function ϕ is taken to be the (general) multiquadric $\phi(x) = (1 + x^2)^{-3/2}$ pictured below. This research is still ongoing.

Methods

We first expand $\phi(x-y)$ in a Taylor series in $\frac{1}{y^n}$, this yields coefficient polynomials $A_n(x)$. If the set of these polynomials span the space of all polynomials, $\Pi[x]$, then the uniform approximation property will follow from the Stone-Weierstrass theorem. A sufficient condition for spanning $\Pi[x]$ involves showing that the leading coefficients of $A_n(x)$ are non-zero.

Proof

We used Maple to generate the first few coefficient polynomials.

$$\begin{aligned} & 1, 3x \\ & 2, 6x^2 - \frac{3}{2} \\ & 3, 10x^3 - \frac{15}{2}x \\ & 4, 15x^4 - \frac{45}{2}x^2 + \frac{15}{8} \\ & 5, 21x^5 - \frac{105}{2}x^3 + \frac{105}{8}x \\ & 6, 28x^6 - 105x^4 + \frac{105}{2}x^2 - \frac{35}{16} \\ & 7, 36x^7 - 189x^5 + \frac{315}{2}x^3 - \frac{315}{16}x \\ & 8, 45x^8 - 315x^6 + \frac{1575}{4}x^4 - \frac{1575}{16}x^2 + \frac{315}{128} \end{aligned}$$

The leading coefficients seems to be $a_n = \binom{n+2}{2}$. The proof showing this pattern was then sought. We have

$$a_n = (-2)^{-n} \sum_{j=\lfloor \frac{n}{2} \rfloor}^n 4^j \binom{-3/2}{j} \binom{j}{2j-n},$$

splitting our problem into two cases, depending on the parity of n , allows us to use a Lemma 1 in [2] to show that $a_n \neq 0$. When n is odd, we can reduce the expression to

$$a_{2M+1} = \frac{(-1)^{M+1}}{2^M M!} \binom{2M+3}{2} \sum_{j=0}^M (-1)^j \binom{M}{j} Q(j)$$

where

$$Q(x) = \frac{(2x+1)(2x+3)\dots(2x+2M+1)}{(M+1)(2M+1)}$$

which is an M^{th} degree polynomial, whose leading coefficient is 2^M . Now we may use Lemma 1 in [2] which provides,

Lemma 1. For $N \in \mathbb{N}$, $0 \leq l \leq N$, and p a polynomial of degree l . We have,

$$\sum_{j=0}^N (-1)^j \binom{N}{j} p(j) = \begin{cases} 0 & 0 \leq l < N \\ (-1)^N a_N \cdot N! & l = N \end{cases}$$

where a_N is the leading coefficient of p .

$$(-1)^{M+1} 2^M M! \frac{(-1)^M}{2^M M!} \binom{2M+3}{2} = \binom{2M+3}{2}$$

which is the desired result when $n = 2M + 1$. The even case is virtually nearly identical.

To clean up this argument, we extended Lemma 1 in [2] to include polynomials of degree $M+1$.

Lemma 2. Suppose $M \in \mathbb{N}$, then we have

$$\sum_{j=0}^M (-1)^j \binom{M}{j} j^{M+1} = (-1)^M M! \binom{M+1}{2}$$

Proof. We calculate this directly from the symmetry in the binomial coefficients. Let $M=1,2,3,\dots$ and consider the sum

$$\sum_{j=0}^M (-1)^j \binom{M}{j} j^{M+1} = \sum_{j=0}^M (-1)^j \binom{M}{M-j} j^{M+1}; \text{ let } k=M-j$$

$$\begin{aligned} &= \sum_{k=M}^0 (-1)^{M-k} \binom{M}{k} (M-k)^{M+1} \\ &= (-1)^{2M+1} \sum_{k=0}^M (-1)^k \binom{M}{k} (k-M)^{M+1} \\ &= - \sum_{k=0}^M (-1)^k \binom{M}{k} (k-M)^{M+1} \end{aligned}$$

where we reindexed, then factored out (-1) to arrive at the last equality. Now adding these expressions together and using Lemma 1 in [2] yields:

$$\begin{aligned} & 2 \sum_{j=0}^M (-1)^j \binom{M}{j} j^{M+1} \\ &= \sum_{j=0}^M (-1)^j \binom{M}{j} [j^{M+1} - (j-m)^{m+1}] \\ &= \sum_{j=0}^M (-1)^j \binom{M}{j} [(M+1)^j M \\ & \quad - \binom{M+1}{2} j^{M-1} M^2 + \dots] \\ &= M(M+1) \sum_{j=0}^M (-1)^j \binom{M}{j} j^M \\ & \quad - M^2 \binom{M+1}{2} \sum_{j=0}^M (-1)^j \binom{M}{j} j^{M-1} + \dots \\ &= 2 \binom{M+1}{2} \sum_{j=0}^M (-1)^j \binom{M}{j} j^M - 0 + 0 - \dots \\ &= 2 \binom{M+1}{2} ((-1)^M M!) \\ &\therefore \sum_{j=0}^M (-1)^j \binom{M}{j} j^{M+1} = (-1)^M M! \binom{M+1}{2} \end{aligned}$$
